## Description

## Technical Field

[0001] The present invention relates to an amine derivative having a melanin-concentrating hormone (hereinafter sometimes to be abbreviated as MCH) antagonistic action and useful as an agent for the prophylaxis or treatment of obesity and the like.

## Background Art

[0002] Feeding behavior is an indispensable action for many organisms including humans. An abnormality in feeding behavior causes deviation from normal life support activities, which in most cases results in diseases. Along with the recent changes in feeding environments, obesity is becoming a social problem. It is widely known that obesity is not only a serious risk factor of life-style related diseases, such as diabetes, hypertension, arteriosclerosis and the like, but also causes arthritis and pain resulting from an excessive burden on knee joints etc. due to increased body weight. In addition, the dieting boom and the like have increased the potential population that desires weight loss. There are many reports on eating disorders, such as hyperphagia and the like, due to neuropathy and the like, which are genetic or caused by stress.

[0003] Consequently, the development and investigation of agents for the prophylaxis or treatment of obesity or feeding deterrents started some time ago, and mazindol has been on the market as a centrally acting anorectic agent.

[0004] Along therewith, a number of appetite-regulating factors represented by leptin have been found in recent years, and new anti-obesity agents and anorectic agents that suppress the activity of such appetite-regulating factors have been developed. Among others, a melanin-concentrating hormone is a hormone derived from hypothalamus and known to have an appetite stimulating action. Furthermore, MCH knockout mouse has been reported to show significantly decreased food intake and be lean, as compared to normal mouse, though normal in daily behavior [see *Nature*, vol. 396, p. 670, 1998]. From the foregoing, an MCH antagonist, once completed, is expected to be a superior anorectic agent or anti-obesity agent.

**[0139]** Preferable examples of the salts with acidic amino acids include salts with aspartic acid, glutamic acid, and the like.

**[0140]** Of these, pharmaceutically acceptable salts are preferable. Preferable examples when compound (I) has an acidic functional group include inorganic salts such as alkali metal salts (e.g., sodium salt, potassium salt, etc.), alkaline earth metal salts (e.g., calcium salt, magnesium salt, barium salt, etc.) and the like, ammonium salts, etc.; and when compound (I) has a basic functional group, inorganic salts such as hydrochloride, sulfate, phosphate and hydrobromide; or organic salts such as acetate, maleate, fumarate, succinate, methanesulfonate, p-toluenesulfonate, citrate and tartrate.

**[0141]** The compound (I) may be an anhydrate or a hydrate. When it is a hydrate, it may contain 0.5 to 3 water molecules.

**[0142]** Furthermore, compound (I) may be labeled with an isotope (e.g., <sup>3</sup>H, <sup>14</sup>C, <sup>35</sup>S, etc.).

**[0143]** Where compound (I) includes optical isomers, stereo isomers, regio isomers and rotational isomers, these are within the scope of compound (I), and can be isolated as their single compound through synthesis or separation known *per se*. For example, where optical isomers of compound (I) exist, those resolved from their mixtures through optical resolution are within the scope of compound (I).

**[0144]** Said optical isomers can be produced by methods known *per se*. Concretely, optically active synthetic intermediates may be used, or mixtures of racemate of the final product are subjected to ordinary optical resolution to give the corresponding optical isomers.

**[0145]** As the optical resolution method, methods known *per se* such as fractional recrystallization method, chiral column method, diastereomer method which are described in detail below and the like are employed.

## 1) Fractional Recrystallization Method

**[0146]** The method which comprises allowing a racemate to react with an optically active compound (e.g., (+)-mandelic acid, (-)-mandelic acid, (+)-tartaric acid, (-)-tartaric acid, (+)-1-phenethylamine, (-)-1-phenethylamine, cinchonine, (-)-cinchonidine, brucine, etc.) to give a salt, which is then isolated through fractional recrystallization method, followed by, when desired, subjecting the isolated compound to neutralization to obtain free optical isomers.

## 2) Chiral Column Method

**[0147]** The method of separating a racemate or a salt thereof, which comprises utilizing a column for fractionating optical isomers (chiral column). In the case of liquid chromatography, for example, a mixture of optical isomers is applied to a chiral column, such as ENANTIO-OVM (manufactured by Tosoh Corp.), CHIRAL SERIES (manufactured by Daicel Co.), and the like, which is then eluted with water, various buffers (e.g., phosphate buffer) and organic solvents (e.g., ethanol, methanol, isopropanol, acetonitrile, trifluoroacetic acid, diethylamine, etc.), singly or as a suitable mixture of them, to isolate the individual optical isomers. In the case of gas chromatography, for example, a chiral column such as CP-Chirasil-DeX CB (manufactured by GL Science Co.), and the like is used for isolation.

## 3) Diastereomer Method

**[0148]** A racemic mixture is chemically reacted with an optically-active reagent to give a mixture of diastereomer, which is subjected to ordinary separation means (e.g., fractional recrystallization, chromatography, etc.) to give single compounds. The thus-isolated single compounds are then chemically processed, for example, through hydrolysis to thereby remove the optically-active reagent site from the compounds to obtain optical isomers. For example, where compound (I) has a hydroxy group or a primary or secondary amino group in the molecule, it is condensed with an optically-active organic acid (e.g., MTPA [ $\alpha$ -methoxy- $\alpha$ -(trifluoromethyl)phenyl-acetic acid], (-)-menthoxyacetic acid, etc.) or the like to give the corresponding ester-type or amide-type diastereomer. On the other hand, where compound (I) has a carboxylic acid group, it is condensed with an optically active amine or alcohol reagent to give the corresponding amide-type or ester-type diastereomer, respectively. The thus-isolated diastereomer is then subjected to acidic or basic hydrolysis, through which it is converted into the optical isomer of the original compound.

**[0149]** The prodrug of the compound (I) means a compound capable of being converted to the compound (I) in vivo by the action of an enzyme or gastric juice and the like under physiological conditions, namely a compound capable of being converted to the compound (I) upon enzymatic oxidation, reduction or hydrolysis and the like, or a compound capable of being converted to the compound (I) upon hydrolysis and the like by gastric juice and the like. As the prodrug of the compound (I), compounds derived by acylation, alkylation or phosphorylation of the amino group of the compound (I) (e.g., compounds derived by eicosanoylation, alanylation, pentylaminocarbonylation, (5-methyl-2-oxo-1,3-dioxolen-4-yl)methoxycarbonylation, tetrahydrofuranylation, pyrrolidylmethylation, pivaloyloxymethylation or tert-butylation of the amino group of the compound (I) etc.); compounds derived by acylation, alkylation, phosphorylation or boration of the hydroxy group of the compound (I) (e.g., compounds derived by acetylation, palmitoylation, propanoylation, pivaloylation, succinylation, fumarylation, alanylation or dimethylaminomethylcarbonylation of the hydroxy group of the compound (I), etc.); and compounds derived by esterification or amidation of the carboxyl group of the compound (I) (e.g., compounds derived by ethyl esterification, phenyl esterification, carboxymethyl esterification, dimethylaminomethyl esterification, pivaloyloxymethyl esterification, ethoxycarbonyloxyethyl esterification, phthalidyl esterification, (5-methyl-2-oxo-1,3-dioxolen-4-yl)methyl esterification, cyclohexyloxycarbonylethyl esterification, or methylamidation of the carboxyl group of the compound (I) etc.), and the like can be mentioned. These compounds can be produced from the compound (I) by methods known per se.

**[0150]** The prodrug of the compound (I) may be one capable of being converted to the compound (I) under physiological conditions, as described in "Iyakuhi no Kaihatsu (Development of Drugs)", vol. 7, Molecular Designing, published by Hirokawa Shoten, 1990, pages 163-198.

**[0152]** In the following [Production Method 1] to [Production Method 3], the compounds for the starting material compound may be used in the form of a salt, respectively. As such salt, those exemplified as the salt of the aforementioned compound (I) can be used.

#### Experimental Example 1 Determination of antagonistic activity of test compound using GTP γ S binding assay

[0809] Using human SLC-1 expression CHO cell clone 57 and rat SLC-1 expression CHO cell clone 44 described in WO01/82925, SLC-1 expression CHO cell membrane fractions were prepared by the following method. In phosphate buffered saline (pH 7.4) supplemented with 5 mM EDTA (ethylenediamine tetraacetic acid) were suspended human and rat SLC-1 expression CHO cells (1x10<sup>8</sup>) and centrifuged. Homogenate buffer (10 ml, 10 mM NaHCO<sub>3</sub>, 5 mM EDTA, pH 7.5) was added to the pellets of the cells and, using Polytron Homogeniser, the mixture was homogenated. The supernatant obtained after centrifugation at 400xg for 15 min was further centrifuged at 100,000xg for 1 hr to give precipitate of the membrane fraction. The precipitate was suspended in 2 ml of an assay buffer [50 mM Tris-HCl (pH 7.5), 1 mM EDTA, 0.1% BSA (bovine serum albumin), 10 mM MgCl<sub>2</sub>, 100 mM NaCl, 1 μM GDP (guanosine 5'-diphosphate), 0.25 mM PMSF (phenylmethylsulfonyl fluoride), 1 mg/ml pepstatin, 20 mg/ml leupeptin, 10 mg/ml phosphoramidon] and centrifuged at 100,000xg for 1 hr. The membrane fraction recovered as precipitate was suspended again in 20 ml of an assay buffer, and after dispensing, preserved at -80°C and used upon thawing each time when in use.

[0810] The antagonistic activity of the test compound was determined as follows. The SLC-1 expression CHO cell

membrane fraction (171  $\mu$ l) diluted with an assay buffer was dispensed to a polypropylene 96 well plate and  $3 \times 10^{-10}$  M MCH (2  $\mu$ l) diluted with DMSO solution, test compound solution (2  $\mu$ l) diluted to various concentrations and [ $^{35}$ S]-Guanosine 5'-( $\gamma$ -thio)triphosphate (25  $\mu$ l, Daiichi Pure Chemicals Co., Ltd.) were respectively added (cell membrane final concentration: 20  $\mu$ g/ml, [ $^{35}$ S]-Guanosine 5'-( $\gamma$ -thio)triphosphate final concentration: 0.33 nM). The reaction mixture was reacted at 25°C for 1 hr with stirring, suction filtered with a glass filter (GF-C) and washed 3 times with a wash solution (300  $\mu$ l, 50 mM Tris-HCl buffer, pH 7.5). Liquid scintillator (50 ml) was added to the glass filter and the residual radioactivity was determined by a liquid scintillation counter.

Binding inhibition (%) = (radioactivity upon addition of test compound and MCH - radioactivity upon addition of DMSO solution) / (radioactivity upon addition of MCH - radioactivity upon addition of DMSO solution) x 100

[0811] From the binding inhibition (%),  $IC_{50}$  of the test compound was calculated. The results are shown in the following.

**Box I Observations where certain claims were found unsearchable (Continuation of item 2 of first sheet)**

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

- 1.
- ☒
- Claims Nos.: 19, 21, 23, 25, 27, 29.

because they relate to subject matter not required to be searched by this Authority, namely:

Claims 19, 21, 23, 25, 27, 29 pertain to methods for treatment of the human body by therapy and thus relates to a subject matter which this International Searching Authority is not required, under the provisions of Article 17(2)(a)(i) of the PCT and Rule 39.1(iv) of the Regulations under the PCT, to search.

- 2.
- ☐
- Claims Nos.:

because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

- 3.
- ☐
- Claims Nos.:

because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

**Box II Observations where unity of invention is lacking (Continuation of item 3 of first sheet)**

This International Searching Authority found multiple inventions in this international application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

**Remark on Protest** ☐ The additional search fees were accompanied by the applicant's protest.

☐ No protest accompanied the payment of additional search fees.
